Coincidence Efficiency Measurement Using $^{11}$B(p,n)$^{11}$C

STEPHEN PADALINO, MEGAN RUSS, DANAE POLSIN, MICHAEL KRIEGER, COLLIN STILLMAN, MOLLIE BIEENSTOCK, DREW ELLISON, ANGELA SIMONE, SUNY Geneseo, MARK YULY, KEITH MANN, TYLER REYNOLDS, Houghton College, CRAIG SANGSTER, Laboratory for Laser Energetics — An attempt to measure the $^{12}$C(n,2n)$^{11}$C cross section for high energy neutrons in the range of 20-30 MeV was conducted using Ohio University’s accelerator facility as a fast neutron source. The neutrons were incident on a graphite target and the $\beta^+$ decay of the activated carbon-11 nuclei were observed in an on-axis gamma ray detector pair. To predetermine the efficiency of this gamma ray detector system, a boron-11 activation experiment was performed. Using SUNY Geneseo’s 1.7 MV tandem pelletron accelerator, 3.1 MeV protons were incident upon the $^{11}$B foil inducing the $^{11}$B(p,n)$^{11}$C reaction to occur at a high rate of activation. The $^{11}$C decays via $\beta^+$ emission, then upon annihilation with an electron creates characteristic 511-511 keV photon pairs which were counted using coincidence methods. Since the $^{11}$B(p,n) cross section is well defined, a calculation was performed to determine the expected number of activations and later compared to the total number of decays observed in the counting system. Funded in part by a grant from the DOE through the Laboratory for Laser Energetics.
